THESIS SUMMARY

The reproductive outcome of plants is often determined by a multitude of interacting factors operating at both the plant level and the population level. For many plants, fruit production and the subsequent release of seeds are paramount for the persistence of the species. Understanding the processes that influence variation within and among populations is therefore crucial for the successful long-term management of threatened plants. While abiotic factors such as resource availability and environmental conditions can influence seed production directly through their effects on plant growth, biological interactions such as those between plants and pollinators or herbivores can be equally important. The relative intensity and direction of such interactions are often determined by the nature of the plants themselves, or by characteristics of the plant population or the habitat in which it occurs.

This thesis examines the processes that influence spatio-temporal variation in the reproductive success of two terrestrial orchids, *Caladenia rigida* and *Caladenia tentaculata*. The study was carried out over three years (2005 – 2007), in several populations located in the Mount Lofty region of South Australia. A detailed investigation of the pollination strategy employed by *C. rigida* revealed that this species is a generalist, being pollinated by a suite of food-seeking insects, possibly attracted by the presence of small amounts of nectar. Successful pollination and seed release for *C. rigida* was highly variable across space and time. Furthermore, both measures were consistently higher than for the sexually deceptive species, *C. tentaculata*, leading to the suggestion that the highly specialised pollination syndrome of the latter species may place it at a reproductive disadvantage. Pollination success of *C. rigida* was influenced by the height of flowers, but not by the local density of conspecifics. Small populations of *C. rigida* did not produce capsules when environmental conditions were stressful, suggesting that resource availability may indirectly restrict reproductive success by limiting the availability of pollinators. Poor seed quality in some populations may also be attributed to reduced population size.

Both orchid species were subject to intense levels of vertebrate florivory and capsule predation, leading to significant reductions in seed output. A herbivore exclusion experiment was carried out to help elucidate the size and type of herbivores, and video-surveillance identified birds as a predominant florivore in some populations. The intensity of florivory varied within and among populations, as well as among years, in response to several factors including flower height, the local density of conspecifics, concealment amongst neighbourhood vegetation and proximity to the habitat edge. Spatio-temporal variation in seed release was thus the net outcome of processes acting on both mutualistic and antagonistic interactions.
This work provides valuable baseline data of factors that influence the reproductive ecology and, hence, population dynamics of *Caladenia* species. Implications for the conservation and management of threatened populations are discussed, with respect to both short-term and long-term goals. The thesis is presented as a series of five manuscripts. Two of these have been published, and the remaining three have been prepared for submission as publications.
Primary thanks must go to my supervisor, José Facelli, for giving me the opportunity to take on this project and for helping me make the transition from molecular biologist to ecologist. His invaluable advice and logical solutions always left me inspired and gave me the confidence to explore my own ideas and directions. Thank you also to Andy Austin, my co-supervisor, for his ongoing support and encouragement, and his excellent and expedient editing skills.

This research was made possible by the financial support provided by a Faculty of Sciences Divisional Scholarship from The University of Adelaide, a Native Vegetation Council Grant and an Australian Research Council Linkage Project (LP0560578) with the Department for Environment and Heritage South Australia, South Australian Museum, Foundation for Australia’s Most Endangered Species, and Biocity Centre for Urban Habitats, University of Adelaide.

Information and advice provided by Joe Quarmby and Doug Bickerton were instrumental in getting this project started. I would also like to acknowledge the members of the Native Orchid Society of South Australia, in particular Bob Bates, Cathy Houston and Peter McCauley, for introducing me to the amazing world of orchids, and for helping locate populations. Thanks also to the many landholders and caretakers who provided access to sites: Bill Pole, Margaret Burton, staff at Forestry SA (especially Jackie Crompton), SA Water, Cleland Conservation Park and Adelaide Hills Council, and the Friends of Ferguson Conservation Park and Scott Creek Conservation Park.

A special thank you to Lachlan Farrington – I really appreciated having a fellow orchid researcher to exchange ideas with, and his sewing skills proved to be particularly useful. I would like to thank all past and present members of the Facelli and Conran labs for their friendship, and for broadening my ecological thinking by exposing me to such a diversity of research projects. I am indebted to Jane Prider for rescuing me from the depths of statistical despair, and thank both Emma Steggles and Jane for debriefing sessions on the bus. Thanks also to Lindy Scott for sharing the PhD highs and lows and reminding me that I was not alone.

The identity of the orchid florivore would remain a mystery were it not for the enthusiasm and creativity of Peter Moyle – he was generous with his time and video equipment, and those cups of tea were especially welcomed after a long day in the field. I am grateful to all of the wonderful people who volunteered their time and keen eye-sight to search for orchids and insects: Remko Leis, John Conran, Kristin Smith, Glenys and Graham Pearce, and David Pearce.
I was extremely fortunate to have had the opportunity to attend orchid conferences and workshops interstate and overseas, and being immersed amongst such brilliant scientists and dedicated conservationists has been a great source of learning and inspiration. I am particularly grateful for the scientific connections and friendships that have developed from these meetings.

A journey such as this would not be possible without the unwavering love and support of family and friends. Thank you to: my mum and dad, Verena and Len, and my brother, Daniel, for always being there for me, and for sharing the excitement of that first ever video footage; and to all of my friends who have stuck by me and provided an understanding ear, especially Cathy. Thanks also to my fiddling friends for helping me exercise the other side of my brain occasionally.

Every good story has a hero, and mine is my amazing husband, David. Words cannot express the immense mental and emotional support he has provided from the outset. This journey of intellectual and personal discovery would not have been completed without his unconditional love, encouragement and patience (not to mention his culinary delights). I look forward to catching up on all of those postponed camping trips to the bush and the coast.
